

Why the Density Profile Inverted: From Bottom-Heavy to Top-Biased

β controls ring spacing: $\beta > 0$ = bottom-heavy, $\beta < 0$ = top-bias. At $n=12$, buckling relaxes – expansion rotor force gradient favours mild top-bias.

$n=3 \rightarrow n=12$

β sign flips from $+0.76$ to -0.13
Per-beam compression drops $4\times$.
Expansion rotor radial force favours hub.
