

The V6.2 Optimization Landscape (Corrected Physics)

Three corrections ($\tan \rightarrow \sin$, $\cos^3 \rightarrow \cos^{2.65}$, coupled knuckles) shifted the optimum to 74.17 kg at $n=12$

1. Convergence: 60 Islands $\times$ 10 000 Steps

Each grey trace = one island population. Green = best island (global best).

Best mass (kg)

grey = individual islands (59 others) green = best island

Bounds: $n \in [3, 12]$, $r_{hub} \in [1, 10]$, $m, \beta \in [-0.8, 0.8]$, $n_{rings} \in [5, 16]$, $n_{exp} \in [0, 6]$, 600k evals

2. Polygon Effect: n_{lines} vs Mass

More lines = thinner beams = smaller knuckles = lower total mass

Best mass (kg)

Each n = separate DE run with all other parameters free

3. Density Profile β : Sign Flip from +0.76 to -0.13

$\beta > 0$ = bottom-heavy (rings cluster low). $\beta < 0$ = top-bias. $\beta = 0$ = uniform spacing.

Mass (kg)

top-bias ($\beta < 0$)

uniform ($\beta = 0$)

bottom-heavy ($\beta > 0$)

The physics correction ($\tan \rightarrow \sin + \cos^{2.65}$) halved the buckling demand, making top-bias optimal

4. Expansion Stations: n_{exp} vs Mass

Expansion rotors sit at ring positions on the shaft (NOT at main rotor). More stations = more mass.

Mass (kg)

$n_{exp}=0$ (no expansion) is heavier than $n_{exp}=1$ — one expansion station at the hub ring provides enough F_r
